1 Introduction

1.1 Question

What is the causal effect of changes in the AEWR (minimum wage paid to H-2A workers) on farmers' utilization of the H-2A program?

1.2 Answer

We find that a $1 increase in the AEWR causes a 3.5% decrease in the number of certified H-2A positions.

1.3 Empirical strategy

The AEWR is set at the regional level. Our unit of observation is counties. Our independent variable is the difference between the AEWR and state minimum wages. Our dependent variable is the number of H-2A positions certified in any given county. We use a triple differences-in-difference setup. Our treatment period are the years post-2011, when there was a large increase in the AEWR. Our first difference compares counties that experienced a relatively larger increase in AEWR to counties that experienced smaller increases. Our second difference compares counties with high vs low pre-existing usage of H-2A workers. Given how the program operates, we expect most of the adjustment to happen on the extensive margin, i.e., farms switching from using domestic labor to using H-2A labor, so we should expect counties with a higher capacity to adjust, or counties with low pre-existing usage, to be "high exposure" counties.

1.4 Why you should care

1.4.1 Food prices

Both the Biden and now the Trump administration have been fighting for years to have AEWR determination procedure changed, to have lower AEWRs. The process has led to multiple lawsuits from farmworkers' unions that have produced injunctions that have blocked policy changes. There is a recognition that the AEWR and the H-2A program more broadly is important to the health of the US agriculture industry, and thus on food prices.

1.4.2 Size

H-2A program is by far the largest migrant labor program in the US, with around 400 thousand workers requested in 2025 alone. Compare with the large amount of ink spilled on the H-1B program, with an annual cap of 25,000 workers. The US agricultural sector is increasingly shifting production to higher value specialty crops (i.e., fruits, tree nuts, vegetables, and horticulture). Specialty crop farming is incredibly labor intensive as many of the crops require manual handling, and thus require large numbers of workers working in the field. However, hiring field workers from the domestic labor pool is notoriously difficult, given the long work hours and unpleasant work conditions. Hence, farmers in the US rely heavily on hiring temporary seasonal farm workers via the H-2A guest worker program. The H-2A program is unique in that it is the only US migrant worker program that is uncapped, and annual usage of the program has increased from $\tilde{8}$0,000 workers in 2008 to $\tilde{3}$84,900 workers in 2024, as shown in figure **??**.

This is in spite of the fact that H-2A workers are significantly more expensive to hire than domestic workers. Even excluding the higher statutory minimum wage paid to H-2A workers (the Adverse Effect Wage Rate), H-2A workers cost an additional $11,000 to $15,000 per worker per year due to housing and transport requirements. The AEWR is set at a regional level by the Department of Labor (DOL) with the stated goal of preventing the hiring of guest workers from depressing the wages of domestic farmworkers.

We plan to extend this research by examining the downstream effects of these labor supply shocks. Specifically, if a higher AEWR reduces access to H-2A labor, how do farmers adapt? Do they shift their production away from labor-intensive specialty crops towards less labor-intensive field crops? Do these shifts in production affect local or regional crop prices?

This paper contributes to several strands of literature. First, we provide...

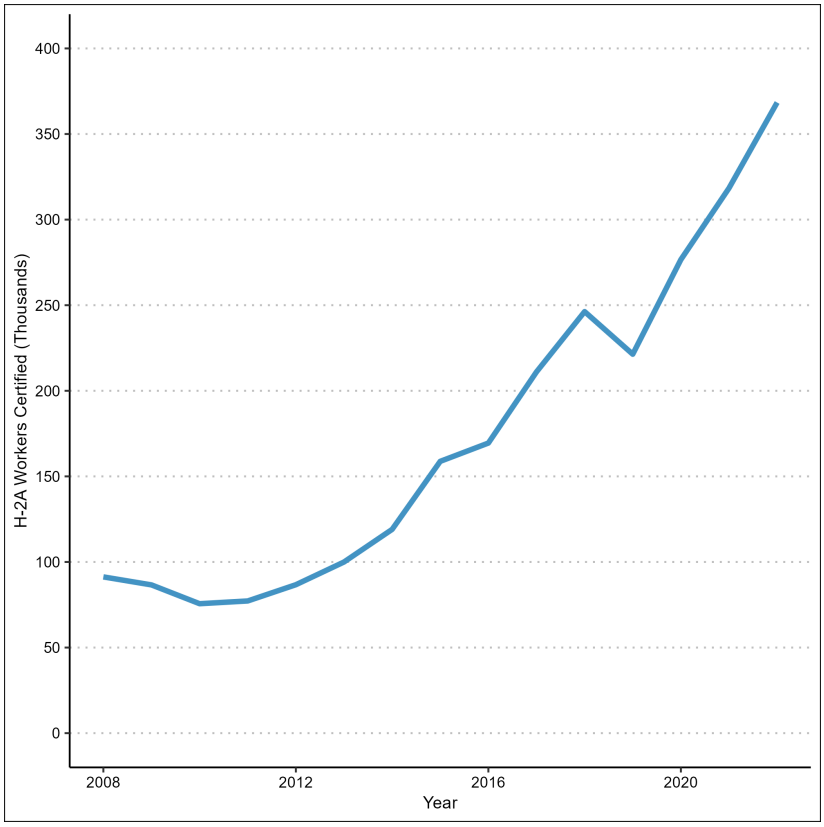

Figure 1: Number of workers certified annually via the H-2A program from 2008 to 2024

2 H-2A agricultural guest worker program

2.1 Background of the program

The Bracero program, which was the forerunner to the H-2A program, was created in 1942 to fill labor shortages due to the war. The program allowed migrant workers, mostly Mexicans, to temporarily work in the U.S. agricultural industry. The program was terminated in 1964, and was succeeded by the H-2A guest worker program which was created as part of the Immigration Reform and Control Act of 1986. The act also created the H-1B and H-2B guest worker programs. The H-2A program is unique in that it is the only U.S. guest worker program that does not have a quota, and as such usage of the program has increased from $\tilde{6}$0,000 in the mid-2000s to $\tilde{5}$00,000 in 2024 today. The H-2A program requires employers to complete an expensive multi-step certification process, involving multiple state and federal agencies. The positions filled via the H-2A program has to be full-time, in the agricultural sector, and seasonal in nature. Note that this traditionally excludes many jobs involving animal husbandry due to their year-round nature.

2.2 H-2A hiring process

The U.S. Department of Agriculture (USDA) and Department of Labor (DOL) provides information to prospective employers who wish to utilize the program (United States Department of Agriculture 2025a; United States Department of Labor 2025b), and I provide a summary of the process for a standard (non-expedited) application. This process begins about 3 months before the actual start of work.

1. The farmer first submits a job order to their state's State Workforce Agency (SWA), which notifies the SWA of the nature of the future H-2A application and requests an inspection of the housing provided by the employer. The SWA, once it accepts the job order, begins domestic recruitment for the job order.

2. The farmer simultaneously applies for labor certification with the Department of Labor's Office of Foreign Labor Certification (OFLC)

3. Once the labor certification application is accepted by the OFLC, the farmer has to begin domestic recruitment for the H-2A positions. The OFLC provides instructions to the farmer for this process. Domestic recruitment may involve:

   - Posting newspaper ads for the positions in a local newspaper that serves the area around the worksite

   - Contacting previously hired domestic workers who were not previously fired for cause or abandoned the job, offering them a position

   - Advertising the position in a maximum of three other states in the region or where they expect to hire (domestic) workers

   The farmer has to interview all domestic applicants and accept every eligible applicant. They also have to maintain a report that includes details of every applicant and contacted former worker, and an explanation of why any given applicant was not hired.

4. Once domestic recruitment has been completed and housing has been inspected by the SWA, the farmer can then apply for final determination of their labor certification with the OFLC

5. After the farmer obtains a labor certification, they can then submit a petition to the United States Citizenship and Immigration Services (USCIS) informing them of the guest workers the farmer intends to hire.

6. Once approved by USCIS, these guest workers will travel to their U.S. consulates to apply for a visa.

7. Once the workers obtain a visa, they can then travel to the U.S. to reach their worksite.

2.3 The Adverse Effect Wage Rate

The Adverse Effect Wage Rate (AEWR) is set by the Department of Labor, and serves as a wage floor for workers hired via the H-2A program. The AEWR is intended to prevent the hiring of H-2A workers from depressing the wages of domestic farmworkers. Farmers have to include information on the wages they intend to pay the workers they hire via the H-2A program, and this wage rate has to equal or exceed the AEWR, the agreed-upon collective bargaining wage, or the federal or state statutory minimum wage, whichever is highest. In practice, the AEWR is typically the relevant wage floor due to the way it is calculated. The DOL calculates the AEWR for different regions in the U.S. based primarily on wage data from the USDA's Farm Labor Survey (FLS), and, for occupations or regions not adequately covered by the FLS, the Bureau of Labor Statistics' Occupational Employment and Wage Statistics (OEWS). These rates are updated and published annually in the Federal Register and on the Department of Labor's website, near the beginning of the year. The AEWR is calculated three different ways depending on the nature of the occupation, and I provide a summary of the DOL's methodology (United States Department of Labor 2025a).

For non-range workers that work in field or livestock occupations, the AEWR is set as an hourly rate, and is calculated from the average wage rates reported for all such such occupations, combined, in the FLS. These occupations are listed by their SOC codes,

- 45-2041 - Graders and Sorters, Agricultural Products.
- 45-2091 - Agricultural Equipment Operators.
- 45-2092 - Farmworkers and Laborers, Crop, Nursery, and Greenhouse.
- 45-2093 - Farmworkers, Farm, Ranch, and Aquacultural Animals.
- 53-7064 - Packers and Packagers, Hand.
- 45-2099 - Agricultural Workers, All Other.

, and they comprise the overwhelming majority of H-2A applications. The AEWR that applies to these occupations is the relevant wage rate for our research. Henceforth, discussion of the AEWR will refer to this rate unless otherwise specified. If any given region or state does not have coverage by the FLS for these

occupations, the average wage rates from the state or national OEWS for these occupations, combined, is used instead. In practice, this only applies to the District of Columbia, Alaska, and U.S. Territories. The regional structure of the non-range field and livestock occupation AEWR is shown in figure **??**. They range from about $19 per hour on the West Coast, to about $14 per hour in the Southeastern Region.

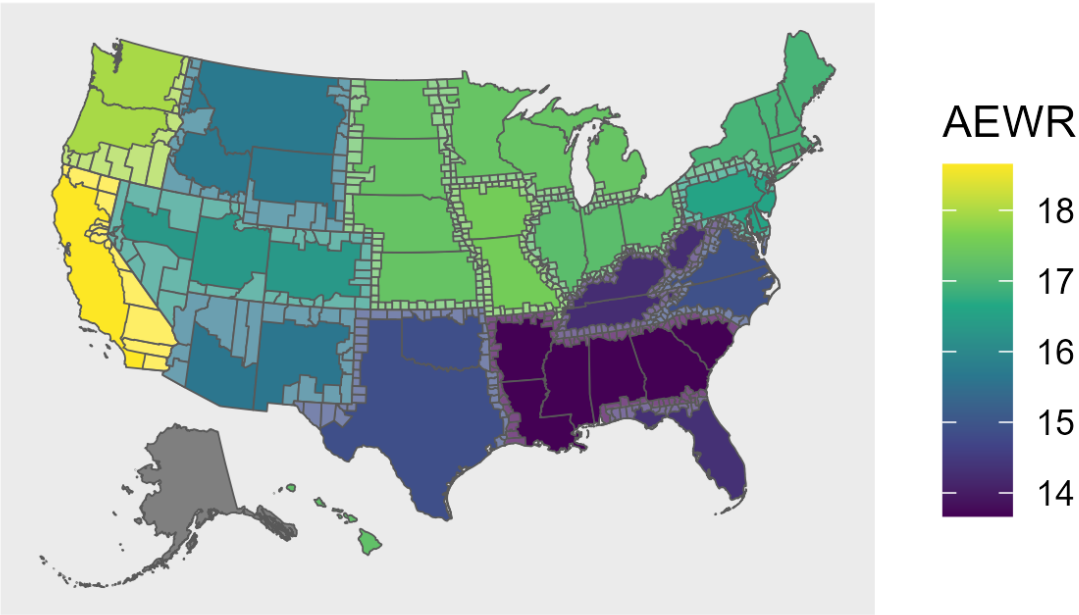

Figure 2: The Adverse Effect Wage Rate in 2023, with border counties highlighted

For all other non-range occupations not already covered, e.g., logging, trucking, and supervisors, the AEWR is set at the state and occupation level. This AEWR in any given state-occupation is simply the mean hourly wage as reported in the OEWS report for that state and SOC code. If the state OEWS is not available, the national OEWS is used instead. In the event that a worker's tasks encompass multiple SOCs, the highest wage rate of those SOCs apply.

For range and animal herding occupations, the AEWR is calculated as a monthly salary, and applies nationally to all workers in this category. Each year's AEWR is the previous year's AEWR inflated by the Bureau of Labor Statistics' Employment Cost Index. The Employment Cost Index is an analogue of the the Producer Price Index or Consumer Price Index, but applied to a fixed "basket" of labor, and measures the hourly cost of hiring labor for US employers, inclusive of benefits. This inflated AEWR is then carried forward into the calculation for next year's AEWR for range and animal herding occupations. This category

of occupations was quite recently added to the H-2A program in 2016, and for that year the monthly AEWR was simply defined as $7.25 (the federal minimum hourly wage), multiplied by 48 hours, and then multiplied by 4.333 weeks per month. This number is then multiplied by 0.8 for 2016, and multiplied by 1 for 2017, and inflated using the index thereafter.

2.4 Additional costs of using the program

Farmers who use the program must pay for the travel costs incurred by the guest workers during this application process, provide or pay for lodgings, provide transportation for their workers' commute to their worksite and for weekly grocery runs, and all associated application fees. This alone incurs anywhere between $10,000 to $14,000 + weekly travel costs per worker hired using the H-2A program (United States Department of Agriculture 2025b).

An addiitonal complication is that employers of H-2A workers have to pay all workers in "corresponding employment" at least the hourly rate they pay their H-2A workers plus an adjustment for the additional costs incurred by H-2A workers, i.e., lodgings and transport.

3 Data sources

3.1 H-2A program usage

The DOL's Office of Foreign Labor Certification (OFLC) posts disclosure files on H-2A program performance data on their website every year. The primary data source consists of H-2A disclosure files from fiscal years 2008 through 2022. These files contain detailed information on every H-2A application received in that year, and include the employer's name and address, the number of workers requested, the nature of the job, worksite addresses, job start and end dates, negotiated hourly wage rates, weekly work hours, and sometimes the relevant crops. The biggest challenge here is in assigning counties to worksites correctly. This is because, prior to 2017, the OFLC only had worksite location data by city, ZIP code, and state. The OFLC only included county information beginning in 2017. This is not even considering errors in data entry or transcription. Hence, I used a multi-tiered approach for matching entries that I cannot directly match on county names. In order of matching priority, from highest to lowest:

1. Direct matching with ZIP codes: The vast majority of entries include ZIP code information. The U.S. Census Bureau provides crosswalks from ZIP codes to counties. Some ZIP codes map to multiple counties, and for those cases I treat the entries as containing multiple counties. I describe further below

how I handle entries with multiple counties.

2. Direct Matching with place names: For entries with reported county names but no ZIP codes, I can just match counties directly. For entries with reported city names but no reported county (mostly entries prior to 2017), the county can be assigned using U.S. Census Bureau files that provide names for all incorporated places within every county. These places would include cities, town, boroughs, and villages. A modified procedure was implemented for New England states, where "towns", equivalent to cities and towns in other states, often serve as the primary unit of local government instead of counties, and thus county information is omitted. In these cases, the worksite "county" entries, which frequently contain town names, were matched with Census place names.

3. Fuzzy String Matching: For worksites that could not be directly matched using either place or county names, a fuzzy string matching approach was used. When county names are available, I first try fuzzy string matching with county names in the Census county file, and select the best match. This takes care of typographical errors in the reported county names. For entries without county names, I calculate string similarity scores between worksite city names reported in the H-2A data and all place names in the Census data contained within the same state. I chose string similarity algorithms and score cutoff thresholds in every individual application manually, choosing one that seemed to minimize false positives while capturing legitimate variations in place names in each context.

4. Google Places API: For the remaining unmatched locations, I utilize Google's Places API as a geocoding solution. These are mostly worksites that are located in unincorporated areas, or reported wity unusual place names, e.g., landmarks, crossroads, etc. This involved a two-step process. First, the "Find Place" endpoint was queried with the reported worksite city and state to obtain a unique location ID. Second, the "Place Details" endpoint was queried with the location ID to retrieve the full address components, including the county name.

The cleaned and geocoded entries were then aggregated to the county-year level. For entries with multiple counties, either because the matched location span multiple counties, or the employer reports multiple worksites for the same workers, I split the man-hours and workers evenly across all the counties within the entry. To account for employment periods spanning across calendar years, the number of workers and man-hours for these applications were weighted by the proportion of the contract period falling within each calendar year.

The final dataset includes the following aggregated variables for each county-year:

- Total number of H-2A workers requested
- Total number of H-2A workers certified
- Total requested man-hours
- Total certified man-hours
- Total number of applications

3.2 Adverse Effect Wage Rates (AEWR)

We collect historical AEWR values from annual notices published the Department of Labor in the Federal Register. I first search for a list of all notices published by the Department of Labor in the Federal Register that contain the keywords "labor certification process" and "adverse effect wage rates". I then wrote a script to download the PDF files of the relevant pages in the Federal Register. The AEWRs are published in a consistent format within the yearly notices, so we can automate the process of extracting the tables and compiling the AEWRs into a dataset that has every state and year.

3.3 Crop acreage

To measure land use patterns, we draw on two USDA National Agricultural Statistics Service (NASS) sources. The first is the Census of Agriculture, conducted every five years (in years ending in '2' and '7'). It provides county-level data on the acreage of hundreds of specific crops. The second is the Cropland Collaborative Research Outcomes System (CroplandCROS) project. This is a project that classifies every 30x30 meter parcel of land in the U.S. by usage and crop type, and publishes the data in their Cropland Data Layer (CDL) product. Each parcel of land corresponds to a single pixel in the CDL. I then assign each pixel to a county, and then aggregate the pixels by county-crop-year.

3.4 Crop prices and yields

We obtain state-level crop prices and yields from agricultural surveys that the NASS conducts every year. While county-level prices and yields would be ideal, they are not systematically available for specialty crops. We also have county-level prices from USDA's Risk Management Agency actuarial data, however this obviously only ccovers specific county-crop-years for which federal crop insurance policies were purchased.

3.5 Occupational Employment and Wage Statistics (OEWS)

The Occupational Employment and Wage Statistics (OEWS) program of the BLS produces estimates of employment and wages for $\tilde{8}30$ occupations across the U.S., by industry and locality. The program surveys every non-farm establishment registered with State Workforce Agencies (SWAs), which excludes most of the agricultural sector. However, the survey does include establishments that fall under NAICS 1151 - Support Activities for Crop Production, which includes establishments engaged in farm labor contracting. Note that the DOL uses OEWS estimates to calculate the AEWR for localities and occupations not adequately covered by the FLS. The estimates are available at the OEWS Metropolitan and Nonmetropolitan Area level, and geographic crosswalks are provided so we can produce estimates at the county level. I calculate the estimates at the county level using the mean of the estimates available within each county by OEWS locality, weighted by the employment estimates. The occupations we are interested in are the same occupations included in the FLS, which are SOC codes

- 45-2041 - Graders and Sorters, Agricultural Products.
- 45-2091 - Agricultural Equipment Operators.
- 45-2092 - Farmworkers and Laborers, Crop, Nursery, and Greenhouse.
- 45-2093 - Farmworkers, Farm, Ranch, and Aquacultural Animals.
- 53-7064 - Packers and Packagers, Hand.
- 45-2099 - Agricultural Workers, All Other.

We can also construct an AEWR wage equivalent by calculating the mean wage for these occupations, which is the same procedure used by the DOL.

3.6 Sample construction

Our geographic sample consists of all U.S. counties that reported having positive amounts of farmland in 2007. Sample period is 2008 to 2024.

4 Empirical design and results

4.1 Sample construction

To estimate the impact of the Adverse Effect Wage Rate (AEWR) on agricultural labor demand, we construct a county-by-year panel dataset spanning the years 2008 to 2024. Our primary outcome variable is the intensity of H-2A program usage, defined as the number of H-2A workers certified in county i during year t, normalized by the county's baseline total farm employment in 2011.

We restrict our estimation sample to counties that reported non-zero agricultural cropland in the 2007 Census of Agriculture.

Our primary explanatory variable is the real AEWR. We define this as the one-year lagged difference between the nominal AEWR and the prevailing state agricultural minimum wage, deflated to real 2012 dollars using the Producer Price Index (PPI).

Finally, we define a county's exposure to the policy. We consider counties with *lower* historical reliance on the H-2A program as high exposure counties, as these counties are the ones that possess the greatest room to adjust their usage of the program when facing domestic wage pressures.

Therefore, we define $HighExposure_i$ as an indicator equal to 1 for counties with pre-existing H-2A usage below the 75th percentile in the baseline period. These low-baseline counties represent the "untapped market" where the policy exerts the strongest influence on program uptake.

4.2. Identification Strategy: Triple Difference (DDD) We exploit variation in the AEWR wage bite across states, over time, and across counties with differing baseline exposure to the H-2A program. We estimate the following continuous Triple Difference (DDD) specification:

5 Model
